

## Notes

### Note in *JER* 11 (Sep, 1) 2007: “Tables in Kamiryo Endogenous World Table (KEWT 1.07) Data-Sets 1960–2005 by Country and by Sector”

Hideyuki Kamiryo

(Received on April 23, 2007)

This note presents my data-sets of nine countries 1960–2005: Russia, China, Korea, Japan, the US, Australia, India, Brazil and Mexico. The data source is *IFSY* and *GFSY*, IMF. Such countries as Russia and China shifted each national accounts system to the SNA 1993 and the periods chosen are shorter than those of other countries. Figures of this note are simultaneously published in *Papers of the Research Society of Commerce and Economics* 48 (Sep, 1). These figures are composed of two parts, **M** and **B**, where M denotes main figures and B denotes business cycle. I will increase the number of countries in KEWT in the near future if I could get budget surplus/deficit and government gross investment by country in IMF data. This is because there are no data-sets that publish capital stock and returns or rents by country and by sector. Penn World Table stopped publishing the capital-labor ratio after 1995 (or, at the time when PWT published 6.1 and 6.5). OECD and Jorgenson researchers will continue publishing capital of the business sector in the future. Nevertheless, it will be difficult for econometric researchers and statisticians to estimate capital and returns by aggregating micro data and to specify those in the government sector. The reason comes from the fact that the macro-level data and the micro-level data cannot be consistently estimated. My data, model, and methods for estimation are based on this fact. My methods depend on my endogenous growth model that integrates, under the discrete case, national accounts and the Cobb-Douglas production function without using random variables. My data, model, and methods rely on national disposable income *NDI* or the sum of consumption and saving, instead of *GDP*. This is justified when I apply a labor function of consumption to my model and methods. And, several of current data are actual, but others are all theoretical so that these theoretical data are not verified by actual data, where *ex-ante* = *ex-post*.

If wages and returns are theoretical so that the sum is equal to *NDI*, the data-set of an economy holds consistently, where capital and returns are also estimated at the macro-level and

by sector. A problem of the SNA is that wages or compensation and operating surplus in *GDP* are only indirectly related to consumption and saving. It is difficult to prove ex-post equilibrium by using the data-set based on *GDP*. It is easy to prove ex-post equilibrium if the data-set based on *NDI* is used. Furthermore, it is easy to prove ex-ante equilibrium over time by using the data-set based on *NDI*, where my model measures the transitional path of all variables endogenously. Under a given Cobb-Douglas production function, my data-set of a country clarifies the relationship between ex-post variables at the current situation and ex-ante variables at convergence. The data by year shifts the Cobb-Douglas production function.

My data-set of the total economy by country is composed of two parts under the rule of aggregate: the government sector and the private sector. In this note first I show two notation tables: Table A-1 for the total economy and Table A-2 for the comparison by sector. Table A-1 shows *actual* values such as population  $L$ , national disposable income  $NDI^1)$  (as the sum of consumption  $C$  and saving  $S$ ) and net investment  $I = \Delta K$ , together with the balance of payment  $BOP$  (as exports less imports plus net primary income from abroad) and budget surplus/deficit. Capital  $K$  and the  $NDI$  (theoretically as the sum of wages  $W$  and returns/rents  $\Pi$ , each modified using the labor function of consumption/utility) are estimated consistently in my endogenous growth model and methods.  $GDP$  after depreciation is composed of actual values of wages, operating surplus, and indirect taxes, where the relationship between wages, operating surplus, and national disposable income is not theoretical.

Nevertheless, the  $BOP$  of the total economy and budget deficit of the government sector are each reliably shown by corresponding saving and investment. To support national disposable income-based data, the framework of  $NDI = W + P = C + S$  must be first of all justified. For this purpose, I will refer to the definitions and framework explained by Rudiger Dornbusch (1980, pp. 19–28). I developed my methods to estimate each  $K$ ,  $W$ , and  $\Pi$ ; in my recent papers, in particular in Kamiryo (IARIW, 2006) using previous data-sets 1995–2004. I will not repeat the methods to estimate capital and returns/rents by sector in this note.

The core of my data-sets is each relationship between consumption and saving in the total economy, the government sector, and the private sector. I assume here that net primary

---

1) There is no terminology of domestic disposable income in the SNA. I have to use national disposable income *NDI* in my data-sets. *NDI* includes net primary income from abroad that is divided into consumption and saving. When an economic stage advances from a young to a developed stage, net primary income from abroad will positively increase as seen in most developed countries such as the US, the UK, and Japan. My data-sets cover countries in different stages and I use *NDI* for comparison in this paper.

income from abroad (interest, dividends, and labor income) is included in *NDI* and *BOP*. Since *NDI* is the sum of consumption and saving, this saving is also national saving (not domestic saving). I indicate that I cannot always obtain the data of net primary income from abroad by country in *IFSY*, IMF. The data of *BOP* is obtained in *IFSY*, but by US\$. I prefer national-accounts data shown by domestic currencies to those shown by US\$.

Now in detail, the relationship between consumption and saving by sector is based on “income *Y*” (not *GDP*). This relationship is expressed by the *BOP* ( $= S - I$ ) in the total economy, by budget surplus/deficit ( $S_G - I_G$ ) in government sector, and by the difference between consumption and saving ( $S_{PRI} + I_{PRI}$ ) in the private sector. This relationship is supported by “the rule of sum” or “the aggregate rule”:  $(S - I) = (S_G - I_G) + (S_{PRI} - I_{PRI})$ . How is this relationship proved? First of all, I indicate a crucial problem in the SNA that the system as statistics cannot theoretically reveal the equality between government returns and government saving. A theoretical relationship between wages and returns in the government sector is justified when the utility/consumption coefficient (*rho/r*) lying in the labor function of consumption is set 1.0 for the government sector. As a result, returns equal saving in the government sector. Each proof for  $S - I$ ,  $S_G - I_G$ , and  $S_{PRI} - I_{PRI}$  is summarized as follows:

1.  $S - I$  as the *BOP*:

Define national disposable income  $Y = C_{PRI} + S_{PRI} + C_G + S_G$  and, total spending<sup>2)</sup>  $E = C_{PRI} + I_{PRI} + C_G + I_G$  in an open economy. In the open economy, disposable income  $Y = C_{PRI} + I_{PRI} + S_G + I_G + X - M$  holds, where  $X - M$  denotes exports less imports plus net primary income from abroad. The difference between *NDI* and spending *E* is  $X - M$ :  $Y - E = X - M$ .<sup>3)</sup>

Because  $Y - E$  equals  $S_{PRI} + S_G - I_{PRI} - I_G$ , an equation of  $S - I = X - M$  is obtained. Therefore, “exports less imports plus net primary income from abroad” equals “saving less investment.”

2.  $S_G - I_G$  as budget surplus (see my indication above):

In the case of Rudiger Dornbusch (1980, Eq. (4a), p. 23), saving of the private sector is defined as  $S_{PRI} \equiv Y - T_{AX} - C_{PRI}$  by using my terminologies and framework, where  $T_{AX} = C_G + S_G = C + S - S_{PRI} - C_{PRI}$ . Also, the government deficit is defined as  $C_G + I_G - T_{AX}$ . Inserting taxes into the equation defined as budget deficit,

---

2) As shown in Eq. (3) of Rudiger Dornbusch ibid., p.20); hereafter, I show his equation numbers, using parenthesis.

3)  $Y \equiv E + (X - M)$  is a good approach of Rudiger Dornbusch (as shown in his Eq. (2a)).

$I_G - S_G = C_G + I_G - C_G - S_G$  is derived. Therefore, budget surplus is shown as  $S_G - I_G$  by changing the sign.

In my case, assuming the utility/consumption coefficient ( $\rho/\alpha$ ) = 1.0,  $W_G = C_G$  and  $\Pi_G = S_G$  hold, where  $Y_G = W_G + \Pi_G = C_G + S_G$ , and budget surplus is defined as  $T_{AX} - (C_G + I_G)$  and equal to  $S_G - I_G$ . When surplus/deficit = 0,  $\Pi_G = S_G = 0$ , where a unique rate of return holds in the whole economy;  $r = r_{PRI}$  (Kenneth Arrow (1972) needs the condition of surplus/deficit = 0). I add  $\Pi_G = S_G$  to any level of deficit. The assumption of  $(\rho/\alpha)_G = 1.0$  is justified from the viewpoint that government should be neutral to consumption or the discount rate of consumption goods,  $\rho$ , equals that of saving. This assumption is also justified by empirical consistencies among parameters and variables in the government sector (see related figures in *PRSCE* 48 (Sep, 1)).

The difference between both proofs is that: Rudiger Dornbusch directly uses the definition of saving in the private sector while mine uses the labor function of consumption:  $1-\alpha = c/(\rho/\alpha)$  by sector. Both results are the same yet, Rudiger Dornbusch cannot explain the process why his definition was derived.

### 3. $S_{PRI} - I_{PRI}$ as the difference between consumption and saving in the private sector:

I proved that the balance of payment in a broad sense and budget surplus/deficit were expressed each using saving and investment as above. As a result, the difference of the private sector is obtained by using  $(S - I) - (S_G - I_G)$ . In short, the framework of  $(S - I) = (S_G - I_G) + (S_{PRI} - I_{PRI})$  holds with its proof, citing the standard paper regarding this equation. My data-sets are based on *NDI* which must correspond with *GDP* domestically produced. This *NDI* is composed of consumption and saving, after depreciation and redistribution of taxes. My framework starts with the balance of payment *BOP* as exports less imports (including factor income from abroad such as (1) interest and dividends of capital and (2) labor income) and budget surplus/deficit. I summarized the essence of my framework, citing the definitions and framework explained by Rudiger Dornbusch (1980, p. 19–28).

Finally, I add a robust reason why I insist on the use of *NDI* instead of *GDP* (or *GNP*, output by residents of a country) in the literature. I was strongly motivated by the analytical results of Paul M. Romer (1987, 1994). Solow's (1956) model exists eternally with an exogenous rate of technological progress expressed as a residual in the Cobb-Douglas production function. However, as analyzed and pointed out by Paul Romer numerically, another problem is still unsolved. This is the measurement of the relative share of capital. Data and methods

go together. When all the data given in statistics are actual then it is convenient for econometrics to compare actual and theoretical results yet, underlying data may be inconsistent and theoretical results will last only a few years due to the character of econometrics.

For example, Paul M. Romer (*The Origins of Endogenous Growth*, *JEP*, 1994, p. 6) points out that the convergence controversy will exist due to an assumption that the same technology is commonly used for the North and South States. Romer shows, in the exogenous growth model, the decisive element is the relative share of capital (expressed as  $\beta$  by Romer). This is because the difference of the rate of technological progress depends on that of the relative share of capital. The key expressions of the relative share of capital are  $1/(1-\beta)$  and  $-\beta/(1-\beta)$ , which influence the rate of technological progress significantly (as empirically shown in Gregory Mankiw, David Romer, and David Weil (1992)). Nevertheless, the range of  $\beta$  varies by country and states. A standard value of  $1/3$  is not enough for a base of implied values of  $\beta$ : Paul Romer indicates various cases numerically. Paul Romer (Table 4 in 1987; 1994, p.8) states that he estimated the value of  $\beta$  to be in the vicinity of 0.25. In my data-sets, I express his  $\beta$  as *alpha*, where *alpha* varies between 0.05 to 0.35 by country, sector, and year. An *alpha* expresses theoretically the value at the macro-level. The corresponding theoretical wage rate does not change even fifty years later and will be compared with the actual wage rate in *GDP* by year for the neutrality of financial assets and possible inflation.

As a preliminary research, Kamiryo (IARIW, 2006) discussed my data-sets 1995-2004 by country and by sector, based on the IMF data for thirty countries. I will discuss further new facts in separate papers towards IARIW, Slovenia, 2008. In short, data and model must go together. Regression analysis or econometric approach only holds for short specific periods and situations. We need more stably equations at the current situation and at convergence, whose verification is done by recursive programming as calibration. The key for a solution is *alpha*, for which first of all I must specify the labor function of consumption, where the utility/consumption coefficient is given as an external value by country as national taste.

#### PS: Future perspectives and for global rules

1. The data-sets by year, country, and by sector in KEWT show all theoretical data except for several current actual data. If the data-set by country treats  $(\rho/\tau)$  and/or the marginal propensity to consume,  $\Delta c = \Delta C/\Delta Y$ , each as a behavioral equation, the data-set will have a few alternatives, which I do not take for simplicity. The verification, therefore, is done only by the consistency of the whole system of data-sets: if theoretical data by year in the data-sets remain unchanged even for forty to fifty years once theoretical data of any year were settled, then this consistency is perfect.
2. I will improve the form of tables in the near future, by adding the following items below. Also, I need to increase the number of countries as many as possible (if deficit and government investment

are continuously available by country).

3. The growth rate of population with employed persons or employees, and the unemployment rate. These data will depend on those in OECD and/or the indicators of the World Bank, 2.1 to 2.4.
4. Analytical comparison of the theoretical wage rate in KEWT (based on the wage function of consumption) and the actual wage rate in *GDP*, whose difference is related to CPI and inflation and more fundamentally to the stop-inequality. The market rate or the central bank interest rate severely exists in the long periods to maintain the neutrality with financial assets.
5. The relationship among the consumption multiplier, the multiplier, and the marginal propensity to consume:  $M_c = M \cdot \Delta c$ , where  $M$  is the inverse number of the marginal capital-output ratio. The marginal propensity to consume,  $\Delta c = \Delta C/\Delta Y$ , will adjust most flexibly the ex-post equilibrium by year in KEWT.
6. Analytical comparison of the valuation ratio,  $v = V/K$ , and the cost of capital,  $r^* - g_Y^*$ , supported by my technology-golden rule corresponding with the Edmund S Phelps's exogenous one. Assets-inflation (or assets-deflation of the government sector as in Japan) and the above inflation/deflation must be each avoided not to be above a certain level, aiming at sustainable growth and sound inequality. I cannot neglect foreign direct investment included in 'domestic.'
7. For sustainable growth and sound inequality, budget control by country and among countries is imperative as indicated by the EU rule. A numerical rule will be found not to damage other countries for international economic co-operations. Also, a certain range of the difference between the theoretical wage rate and the actual wage rate must be set as a global standard or rule not to deepen inequality among people.

Note that each table series are composed of four tables. Some marginal ratios are omitted in these series.

Note in JER 11 (Sep, 1) 2007: "Tables in Kamiryo Endogenous World Table (KEWT 1.07)  
Data-Sets 1960–2005 by Country and by Sector"

**Table A-1 Notations of values and ratios of the total economy as a base**

L Labor or population	$Y_G/Y$	The ratio of government NDI to the total economy $NDI$
n The growth rate of population	$K_G/K$	The ratio of government capital to the total economy capital
BOP=Ex-Im Exports less imports; $BOP$ in a narrow sense= $S - I$	alpha	The relative share of returns/rents/capital to $NDI$
Bud deficit Budget surplus/deficit= $S_G - I_G$ in the G sector	(r/w)	The ratio of the rate of return to the wage rate
AK <sub>GROSS</sub> Gross capital investment; $I_{GROSS}$	w=W/L	The wage rate (for convenience, I assume $w=w_G=w_{PRI}$ )
Depreciation Capital consumption	gw	The growth rate of the wage rate
AK <sub>NET</sub> Net capital investment after depreciation; $I_{NET}$	gr	The rate of change in the rate of return
C Consumption	k=K/L	The capital-labor ratio
S Saving; net saving	$K=K_0+\Delta K$	Capital as the sum of the previous stock plus net investment
Y=NDI National disposable income=C+S	$\Omega=K/Y$	The capital-output ratio, where output= $NDI$
W=(1- $\alpha$ )Y Compensation/wages; alpha is the relative share of labor	TFP	Total factor productivity as an input stock= $k^{(1-\alpha)}/\Omega$
S <sub>G</sub> =Bud+I <sub>G</sub> Government saving=( $S_G - I_G$ )+ $I_G$	$g_{TFP}$	The growth rate of $TFP$
y=Y/L Per capita $NDI$	$g_L$	The growth rate of the capital-labor ratio
g <sub>y</sub> The growth rate of per capita $NDI$	$g_A$	The growth rate of tech. progress $g_A(t) = i(1-\beta)(t)k(t)^{\alpha-\delta}$
i=I/Y The ratio of net investment to $NDI$	$g_A/g_{TFP}$	The ratio of $g_A$ to $g_{TFP}$ ; if it is 1.0, $alpha$ is constant over years
0=i/s The ratio of net investment to saving	$g_w/g_y$	The ratio of $g_w$ to $g_y$ ; if it is 1.0, $alpha$ does not change.
c=C/Y The ratio of consumption to $NDI$	$B^*(1-\beta^*)/\beta^*$	The ratio of qualitative to quantitative investment at convergence
(rho/r) The consumption coefficient. $rho$ is time preference.	$\beta^*=beta^*$	The ratio of quantitative investment to total net investment
= $\alpha/\Omega$ The rate of return; the ratio of returns/rents to capital	$s-i=BOP/NDI$	The growth rate of $BOP=(S-I)$ to $NDI$
r <sub>CB</sub> Central Bank discount rate or the market rate	$S_G/I_G=Budget$	The ratio of Budget=( $S_G - I_G$ ) to $NDI$
c <sub>CB</sub> =r/r <sub>CB</sub> The coefficient of financial asset neutrality	$S/S/NDI$	The ratio of saving to $NDI$ or the saving rate
delta A parameter that neutralizes diminishing returns to capital	$\Omega_G$	The capital-output ratio of the government sector
$1/\lambda$ The years for convergence; $1/\lambda=1/(1-\alpha)+(1-\delta)g_A$	$\Omega_{PRI}$	The capital-output ratio of the private sector
sigma The elasticity of $k$ w.r.t. ( $r/w$ ) $\eta=(\Delta k/k)/(\Delta(r/w))/(r/w)$		

Notes:

- (1) My framework of  $BOP$  as exports net,  $(S-I)=(S_G-I_G)+(S_{PRI}-I_{PRI})$ , is based on  $NDI$ , where budget deficit ( $S_G - I_G$ ) equals Taxes less  $C_G$ . Here  $NDI$  is actually domestic disposable income since we cannot obtain factor income from abroad by country in IMF data. My framework is consistent with the framework of Rudiger Dornbusch (1980, pp.19-28) based on  $GDP$  or  $GDP$ . I will discuss this issue in Kamiryo (JARIW, 2008).
- (2) For China and Russia,  $(rho/r)=1.8075*c^2-2.22549*c+1.4688$ . For Japan,  $(rho/r)=1.4672*c^2-0.9273*c+0.6983$ . For the US,  $(rho/r)=3.0095*c^2-3.0426*c+1.4193$ .
- (3) For ( $r/w$ ) by country and by sector, use 'goal seek' to ( $r/w$ ) as a goal, by making  $K=kL$  (where  $k=(\alpha/(1-\alpha))/(r/w)$ ) equal to  $K=K_0+\Delta K$ .  $(rho/r)$  is definitely an external parameter. But,  $(r/w)$  is an external parameter only if  $K=L(\alpha/(1-\alpha))/(r/w))$  is not connected with  $K=K_0+\Delta K$ .

**Table A-2 Notations of values and ratios by sector: the government and private sectors**

(rho/r)=rho/r The utility/consumption coefficient of the total economy	$g_{TFP}$	The growth rate of $TFP$ in the total economy
(rho/r) <sub>G</sub> =rho <sub>G</sub> / The utility coefficient of the government sector	$g_{TFP(G)}$	The growth rate of $TFP$ in the government sector
(rho/r) <sub>PRI</sub> The utility coefficient of the government sector	$g_{TFP(PRI)}$	The growth rate of $TFP$ in the private sector
(r/w) The ratio of the rate of return to the wage rate	$g_A$	The growth rate of tech progress in the total economy
(r/w) <sub>G</sub> The ratio of the rate of return to the wage rate in G	$g_{A(G)}$	The growth rate of tech progress in the government sector
(r/w) <sub>PRI</sub> The ratio of the rate of return to the wage rate in PRI	$g_{A(PRI)}$	The growth rate of tech progress in the private sector
k=K/L The capital-labor ratio of the total economy	$g_A/g_{TFP}$	The ratio of $g_A$ as the flow level to $g_{TFP}$ as the stock level
$k_G=K_G/L_G$ The capital-labor ratio of the total economy in G	$g_A(g_{TFP(G)})$	The ratio of $g_A$ to $g_{TFP}$ in the government sector
$k_{PRI}=K_{PRI}/L_{PRI}$ The capital-labor ratio of the total economy in PRI	$g_A(g_{TFP(PRI)})$	The ratio of $g_A$ to $g_{TFP}$ in the private sector
TFP=k <sup>alpha</sup> /Omega Total factor productivity of the total economy	$i=I/Y$	The ratio of net investment to national disposable income $NDI$
TFP <sub>G</sub> Total factor productivity of the government sector	$i_G=I_G/Y_G$	The ratio of net investment to $NDI$ in the government sector
TFP <sub>PRI</sub> Total factor productivity of the private sector	$i_{PRI}=I_{PRI}/Y_{PRI}$	The ratio of net investment to $NDI$ in the private sector
$alpha=\Pi/Y$ The relative share of capital/rents of the total economy	$g_A^*$	The growth rate of tech progress at convergence
$\alpha_G=\Pi_G/Y_G$ The relative share of capital/rents of the G sector	$g_{A(G)}^*$	The growth rate of tech progress at convergence in the G sector
$\alpha_{PRI}=\Omega_{PRI}/Y_{PRI}$ The relative share of capital/rents of the PRI sector	$g_{A(PRI)}^*$	The growth rate of tech progress at convergence in the PRI sector
$r=\Pi/K$ The rate of return of the total economy	$B^*$	The ratio of qualitative to quantitative investment at convergence
$r_G=\Pi_G/K_G$ The rate of return of the government sector	$B_G^*$	The ratio of qualitative to quantitative investment at convergence in G
$r_{PRI}=\Pi_{PRI}/K_{PRI}$ The rate of return of the private sector	$B_{PRI}^*$	The ratio of qualitative to quantitative investment at convergence in PRI
$\sigma=\eta(k/(r/w))$ Elasticity of substitution of the total economy	$\delta$	A parameter that neutralizes diminishing returns to capital
$\sigma_G$ Elasticity of substitution of the government sector	$\delta_{G}$	A parameter that neutralizes diminishing returns to capital in G
$\sigma_{PRI}$ Elasticity of substitution of the private sector	$\delta_{PRI}$	A parameter that neutralizes diminishing returns to capital in PRI
gy The growth rate of per capita $NDI$ in the total economy	$1/\lambda$	The years for convergence of the total economy: $\lambda$ is conv. coefficient
$g_{y(G)}$ The growth rate of per capita $NDI$ in the G sector	$1/\lambda_G$	The years for convergence of the G sector: $\lambda$ is conv. coefficient
$g_{y(PRI)}$ The growth rate of per capita $NDI$ in the PRI sector	$1/\lambda_{PRI}$	The years for convergence of the PRI sector: $\lambda$ is conv. coefficient

Notes:

- (1) By an accounting identity, expenditures  $C_G$  equals wages  $W_G$  in the government sector:  $C_G=W_G$ , where saving equals returns,  $S_G=P_G$ . By setting  $w=w_G=w_{PRI}$ , the share of government labor to labor is settled: (1)  $(rho/r)_G=1.0$ , (2)  $w=r/(r/w)$ , (3)  $L_G=L(W_G/W)$ , and (4)  $w=w_G=W_G/W$ .
- (2) By comparing each of values and ratios of the total economy, the government sector and the private sector, economic and fiscal policies are evaluated. I stress that the review of the values and ratios of the total whole economy is not enough to clarify the real movements of economic and fiscal policies.

**Table R1-1 Russia 1993–2005, using ( $\rho/\bar{r}$ ) specified as Russia national taste**

Amounts	L	n	BOP=Ex-In	Bud deficit	$\Delta K_{GROSS}$	Depreciation	$\Delta K_{NET}$	Consumptio	Saving, S	Y=NDI	$W=(1-\alpha)Y$	$S_G=Bud+I_G$
